

MALIGNANT COMMENTS CLASSIFICATION

Submitted by: Haindavi Chakravarthi

Internship: 23

ACKNOWLEDGMENT

- The successful completion of any work would be always be incomplete unless we mention the valuable cooperation and assistance of those people who were a source of constant guidance and encouragement, they served as bacon light and crowned our efforts with success.
- First of all, I would like to thank all my mentors in Data Trained and FlipRobo Technologies for this opportunity.
- ➤ I wish to express our sincere thanks to the above people, without whom I would not have been able to complete this project.

MALIGNANT COMMENTS CLASSIFICATION

- ✓ which also helped me in doing a lot of research and I came to know about so many new things on the Natural language processing project I am thankful to them.
- ✓ Secondly, I would also like to thank my parents who helped me a lot in finalizing this project within the limited time frame.

INTRODUCTION

Business Problem Framing

There has been a remarkable increase in the cases of cyberbullying and trolls on various social media platforms. Many celebrities and influences are facing backlashes from people and have to come across hateful and offensive comments. This can take a toll on anyone and affect them mentally leading to depression, mental illness, self-hatred, and suicidal thoughts.

Our goal is to build a prototype of online hate and abuse comment classifier which can be used to classify hate and offensive comments so that they can be controlled and restricted from spreading hatred and cyberbullying.

Conceptual Background of the Domain Problem

The conceptual background of the problem depends on the language and words which make any comment toxic or neutral, our main motto is to find those words which are highly malignant.

Review of Literature

Data exploration is the first step in data analysis and typically involves summarizing the main characteristics of a data set, including its size, accuracy, initial patterns in the data, and other attributes. It is commonly conducted by data analysts using visual analytics tools, but it can also be done in more advanced statistical software, Python. Before it can analyze data collected by multiple data sources and stored in data warehouses, an organization must know how many cases are in a data set, what variables are included, how many missing values there are, and what general hypotheses the data is likely to support. An initial exploration of the data set can help answer these questions by familiarizing analysts with the data with which they are working. We divided the data 8:2 for Training and Testing purposes respectively.

Motivation for the Problem Undertaken

Every problem of Machine learning gives us chance to enhance and develop problem-solving skills. These Problems do's the same.

When this real-life problem of predicting whether the comments to anybody is legal or not which kind of words are used and how much they are toxic to someone, whether to rely on old data or new data words are words they are accepted globally important and with help of A. I technology we make a completely new model of detection. As Data scientists it is our role to help and understand the market better with newer data, for constructing real-life helpful models for companies.

In this project, we have a dataset of comments and their categories of how lethal they are, for that, we have to analyze

those features which make comments toxic and help companies to build the detection models for filtration and stopping such comments for plotting.

Analytical Problem Framing

Mathematical/ Analytical Modeling of the Problem
 As for any basic model building, we have to understand the
 type of target variable, the data of the target variable is
 continued or classified.

Data Analysis is always the difficult part, for better understanding different kinds of bar plots, distribution plots are created with the target Column for finding the insights of the dataset we have.

Analytical Modelling always starts with the target variable we have, and in that case, our target variables are text comments first we have to filter them and make data clean then using different analysis tools select the list of toxic words which makes comments malignant, for that, we create some distribution plots with the target variable to understand which feature columns help to learn the model best and which feature columns reduce the accuracy of the model.

And after finding the relation and correlation with the target variable we choose either Regression Model or Classification Model. Here in this problem, our target feature column is classified so we build our Machine Learning model on classification.

Data Sources and their formats

Data Set Description

The data set contains the training set, which has approximately 1,59,000 samples, and the test set which contains nearly 1,53,000 samples. All the data samples contain 8 fields which include 'Id', 'Comments', 'Malignant', 'Highly malignant', 'Rude', 'Threat', 'Abuse' and 'Loathe'. The label can be either 0 or 1, where 0 denotes a NO while 1 denotes a YES. There are various comments which have multiple labels. The first attribute is a unique ID associated with each comment.

The data set includes:

Malignant: It is the Label column, which includes values 0 and 1, denoting if the comment is malignant or not.

Highly Malignant: It denotes comments that are highly malignant and hurtful.

Rude: It denotes comments that are very rude and offensive.

Threat: It contains an indication of the comments that are giving any threat to someone.

Abuse: It is for abusive comments.

Loathe: It describes the hateful comments and loathing in nature.

ID: It includes unique Ids associated with each comment text given.

Comment text: This column contains the comments extracted from various social media platforms.

This project is more about exploration, feature engineering, and classification that can be done on this data. Since the data set is huge and includes many categories of comments, we can do a good amount of data exploration and derive some interesting features using the comments text column available.

Data set looks as follows.

	id	comment_text	malignant	highly_malignant	rude	threat	abuse	loathe

Here we have described the train and test data where we can see that in train data the minimum value starts from 0 and even they 50% and 75% quantile are also 0

Data Preprocessing Done

This project is based on NLP and we have comments or string data for that we have to first convert comments into words then filter and cleaning of data using several libraries and finally convert them into int datatype.

- 1. **Data Extraction:** It is the first step of any model. most data is in CSV or excel format and for analyzing the data we use the data manipulation tool pandas and NumPy after that data is converted into a data frame for analyzing the data.
- 2. **Data Cleaning:** First we clean the data which have no use in prediction like the S.no column and Id, then we drop the data which has a high no of missing percentages.
- Stemming And Lemmatisation: The next step is to tag the words via Text Part Of Speech Tagging. Additionally, we are ready to perform Stemming And Lemmatisation In The NLP Data Science Project.
- 4. Text Mining Algorithms: The text needs to be converted to numbers. Multiple algorithms compute and use the frequency of the words or group them to help us understand their hidden meanings.
- 5. Word2Vec Algorithm: Now the numerical data needs to be fed into a model so that we can start forecasting it. We can feed our data to a model. Word2Vec algorithm is gaining popularity. Let's understand how to Predict Text Using
- 6. **Data transformation** is the process of changing the format, structure, or values of data; we use a labeled encoder for coding the object data into integer data.
- 7. Data Reduction: it is the process of finding the most correlated columns, and combining them because the machine does not understand which feature columns impact the most on accuracy.

- 8. **Data discretization** converts a large number of data values into smaller once, so that data evaluation and data management becomes very easy, using box plots is makes a clear understanding of the data.
- Evaluate NLP Model: Now that the NLP algorithm has started to forecast text, the last step is about assessing the accuracy of the model. Learn How To Evaluate The Model Performance

• Data Inputs- Logic- Output Relationships

Regression and classification models are important tools for researchers in various fields. The application of these many-to-one mapping models is two-fold. First, they can be used for prediction. The output value or class of a (new) case can be predicted by applying the inferred mapping to the input variables of the case. Second, they inform us about the relationship between the input and the output. They specify how the input variables are (mathematically) interacting with each other to produce the output variable. The usefulness of the second application is, however, limited by the power of the human intellect. We suggest that the interpretation of these many-to-one mapping models is of utmost, yet undervalued, importance in many research fields.

State the set of assumptions (if any) related to the problem under consideration

As we are trying to predict the malignant in comments and build a filtration model using M.L for predicting whether a comment is malignant or not for this we assume that the bad words are almost the same which makes any comments toxic.

Hardware and Software Requirements and Tools Used

Python is widely used in scientific and numeric computing: SciPy is a collection of packages for mathematics, science, and engineering.

Pandas are data analysis and modeling libraries.

Natural Language Toolkit: NLTK is a leading platform for building Python programs to work with human language data. It provides easy-to-use interfaces to over 50 corpora and lexical resources such as WordNet, along with a suite of text processing libraries for classification, tokenization, stemming, tagging, parsing, and semantic reasoning, wrappers for industrial-strength NLP libraries,

Libraries Used for this Project include –

- 1. Pandas
- 2. NumPy
- 3. Matplotlib
- 4. Seaborn
- 5. Scikit Learn
- 6. Nltk
- 7. WordNetLemmatizer
- 8. TF-IDF vactorrization

Model/s Development and Evaluation

Identification of possible problem-solving approaches (methods)

After analyzing the dataset, I observe that many of the feature columns are int type and coment_text is string type. so first, we have to convert them into an integer so that the machine interprets the data and for that, we use the NLP toolkit for all the features columns.

Then find the correlation between the columns with target columns and delete the non-related feature columns.

We observe that the target column is skewed.

After converting text into int datatype and classes are defined.

The target column is classified so we start work on Classification models building.

Testing of Identified Approaches (Algorithms)

List down all the algorithms used for the training and testing.

- 1. Logistic Regression
- 2. DecisionTreeClassifier
- 3. Random forest Regression.
- 4. Xgboost
- 5. AdaBoostClassifier
- 6. KNeighborsClassifier

Run and Evaluate selected models

Logistic Regression Model

- Logistic Regression is a machine learning algorithm based on supervised learning.
- It performs a regression task. Regression models a target prediction value based on independent variables.
- It is mostly used for finding out the relationship between variables and forecasting.

from above we easily find out that

Precision, recall,fl-score from the above plotting.

Our model performs well on the initial level

2. DecisionTreeClassifier

DecisionTreeClassifier is a class capable of performing multiclass classification on a dataset.

As with other classifiers, DecisionTreeClassifier takes as input two arrays: an array X, sparse or dense, of

shape (n_samples, n_features) holding the training samples, and an array Y of integer values, shape (n_samples,), holding the class labels for the training samples: `

DecisionTreeClassifier

```
DT = DecisionTreeClassifier()
DT.fit(x_train, y_train)
y_pred_train = DT.predict(x_train)
print('Training accuracy is {}'.format(accuracy_score(y_train, y_pred_train)))
y pred test = DT.predict(x test)
print('Test accuracy is {}'.format(accuracy_score(y_test,y_pred_test)))
print(confusion_matrix(y_test,y_pred_test))
print(classification report(y test,y pred test))
Training accuracy is 0.9988898736783678
Test accuracy is 0.9394844585561497
[[41567 1383]
 [ 1514 3408]]
             precision recall f1-score support
                  0.96 0.97
0.71 0.69
                                             42950
                                      0.97
                                      0.70
                                               4922
                                     0.94 47872
   accuracy
macro avg 0.84 0.83 0.83 47872
weighted avg 0.94 0.94 0.94 47872
```

Observations:

- 1. This Decision Tree classifier Performs with 87% accuracy for predicting frauds.
- 2. After predicting and plotting the predicted data on the best fit line we observe that DT-C is not so accurate.
- 3. CV is not well. And does not give accurate results.

0.9401848660504465 accuracy score.

RandomForestClassifier

A random forest is a meta estimator that fits several decision tree classifiers on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. The sub-sample size is controlled with the max_samples parameter if bootstrap=True (default), otherwise the whole dataset is used to build each tree.

XGBoost Classifier

XGBoost provides a wrapper class to allow models to be treated like classifiers or regressors in the sci-kit-learn framework. This means we can use the full sci-kit-learn library with XGBoost models. The XGBoost model for classification is called XGBClassifier. We can create and fit it into our training dataset. Models are fit using the sci-kit-learn API and the model. fit() function. Parameters for training the model can be passed to the model in the constructor.

xgboost

```
import xgboost
xgb = xgboost.XGBClassifier()
xgb.fit(x_train, y_train)
y pred train = xgb.predict(x train)
print('Training accuracy is {}'.format(accuracy_score(y_train, y_pred_train)))
y_pred_test = xgb.predict(x_test)
print('Test accuracy is {}'.format(accuracy_score(y_test,y_pred_test)))
print(confusion_matrix(y_test,y_pred_test))
print(classification_report(y_test,y_pred_test))

Key Metrics for success in solving the problem under consideration

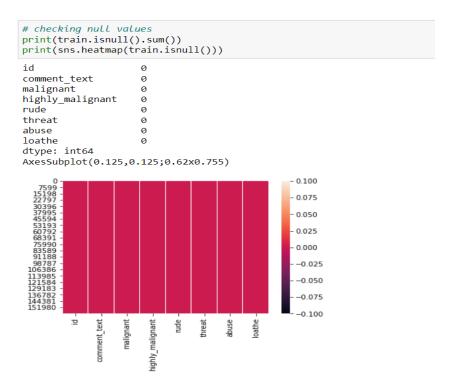

Confusion matrix, Mean Absolute Error, Mean Squared Error, Root Mean Square Error

This matrix helps to understand the model more deeply.

• Visualizations

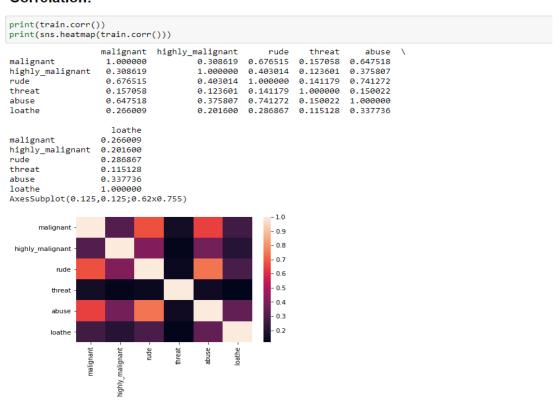

Data visualization is the graphical representation of information and data. By using charts, plots, and graphs data visualization tools provide an accessible way to see and understand trends, outliers, and patterns in data.

In the world of Big Data, data visualization tools and technologies are essential to analyze massive amounts of information and make data-driven decisions.

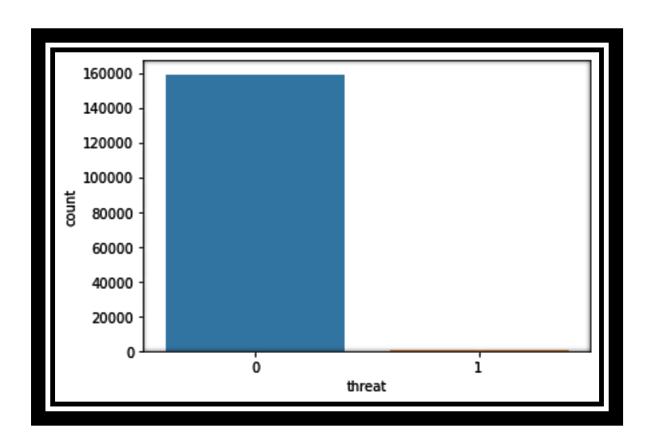

As clearly we analyze that no-null values are present.

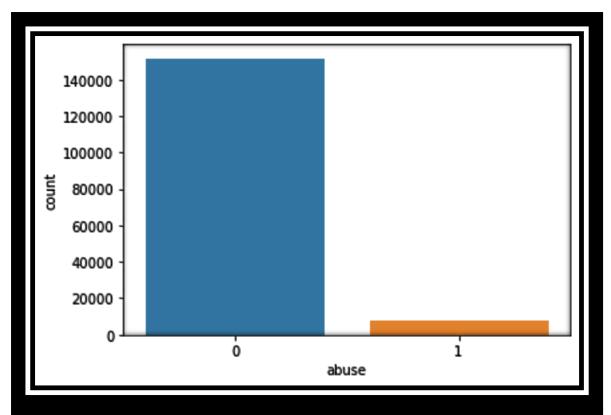

Correlation:

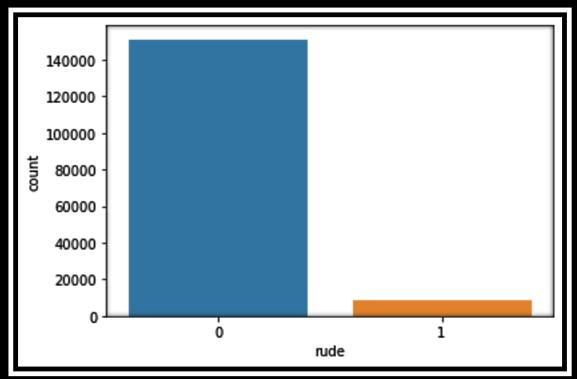

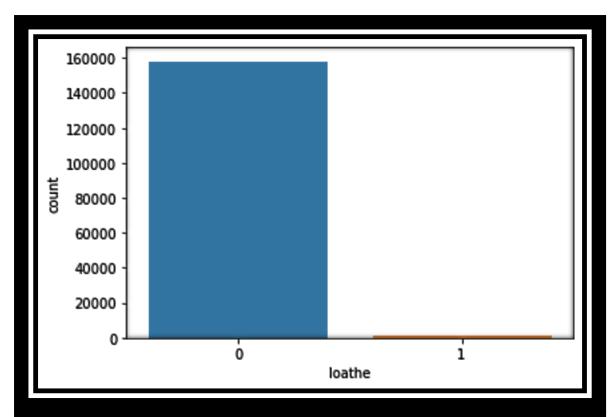

No feature columns are negatively co-related with target columns.

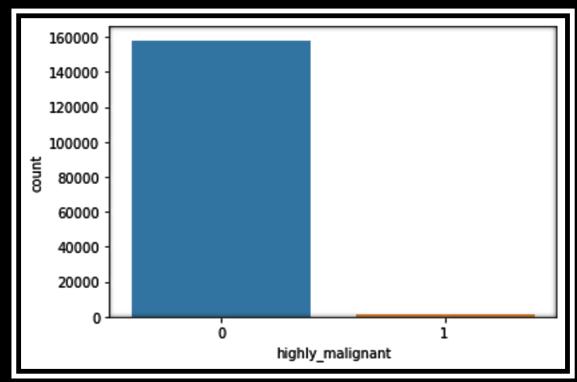

Abuse is highly related to malignant

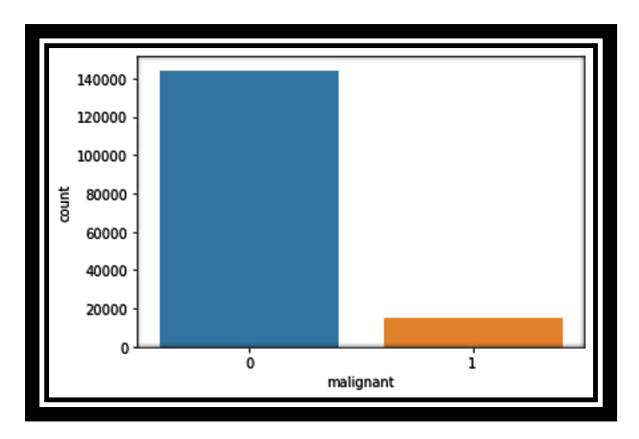

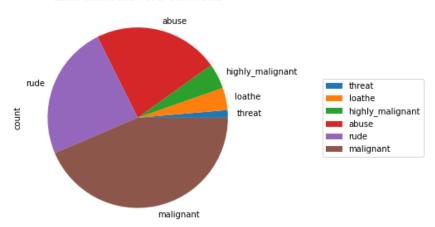

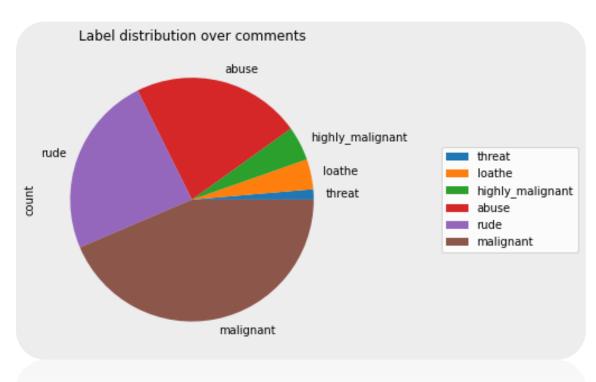

Distribution plotting of different features columns.

And from the above plotting, it is mentioned that the count of normal comments is more than as compared to toxic comments.

<matplotlib.legend.Legend at 0x225e9c71d60>

Label distribution over comments

malignant

Plotting of sections of different feature columns and we observe that malignant comments are more as compared to remaining one.

• Interpretation of the Results

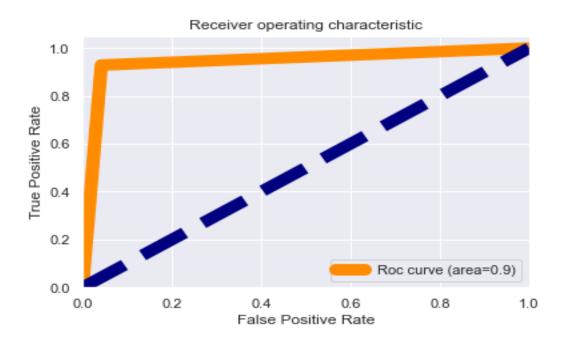

List of accuracy scores of different classification models

logistic Regression: - 0.9557888140372865

Dicision Tree Classifier: - 0.9382422058593138 Random Forest classifier: - 0.9555694814350619

xgboost:- 0.9528434905216983

AdaBoostClassifier: - 0.949114836283879 KNeighborsClassifier: - 0.917781607394642

observations:

- 1. Roc curve area is 0.9 which means that our model is distinguish ed between the malignant comment or not.
- 2. our model understands that label 0 is 95% different than label 1, which is good.
- 3. It means there is a 95% chance that the model will be able to d istinguish between positive class and negative class.

CONCLUSION

We tested out different models for training and testing on our given dataset and after all the training and testing on different models we find out that Random Forest Regression performed above all.

Key Findings and Conclusions of the Study

So, our Aim is achieved as we have successfully ticked all our parameters as mentioned in our Aim Column. It is seen that nltk libraries help us to find the outcomes. All the feature columns are positively co-related.

Our model accuracy is over 95% which is good in terms of initial model building.

Learning Outcomes of the Study in respect of Data Science

Throughout this kernel, we put into practice many of the strategies for predicting whether comments are malignant or not. We philosophized about the variables, we analyzed 'Comment_text' alone and with the most correlated variables, we tested some of the fundamental statistical assumptions and we even transformed text data into int32 type. That's a lot of work that Python helped us make easier.

• Limitations of this work and Scope for Future Work

As we do lots of research and our data set is quite big which helps us to find different toxic words from around the world which makes this study successful still as generations are evolved and continuously discovering new slag words which make comments toxic. we don't rely on this data for too long continuously adding more stopwords in the nltk library for helping us to make more powerful models and make us future-ready.
